Abstract

Toxicity annotators and content moderators often default to mental shortcuts when making decisions. This can lead to subtle toxicity being missed, and seemingly toxic but harmless content being over-detected. We introduce BIASX, a framework that enhances content moderation setups with free-text explanations of statements' implied social biases, and explore its effectiveness through a large-scale crowdsourced user study. We show that indeed, participants substantially benefit from explanations for correctly identifying subtly (non-)toxic content. The quality of explanations is critical: imperfect machine-generated explanations (+2.4% on hard toxic examples) help less compared to expert-written human explanations (+7.2%). Our results showcase the promise of using free-text explanations to encourage more thoughtful toxicity moderation.

1 Introduction

Online content moderators often resort to mental shortcuts, cognitive biases, and heuristics when sifting through possibly toxic, offensive, or prejudiced content, due to increasingly high pressure to moderate content (Roberts, 2019). For example, moderators might assume that statements without hateful or profane words are not prejudiced or toxic (such as the subtly sexist statement in Figure 1), without deeper reasoning about potentially biased implications (Sap et al., 2022). Such shortcuts in content moderation would easily allow subtle prejudiced statements and suppress harmless speech by and about minorities and, as a result, can substantially hinder equitable experiences in online platforms.[1] (Sap et al., 2019; Gillespie et al., 2020).

To mitigate such shortcuts, we introduce BIASX, a framework to enhance content moderators' deci-

Figure 1: To combat "thinking fast" in online content moderation, we propose the BIASX framework to help moderators think through the biased or prejudiced implications of statements with *free-text explanations*, in contrast to most existing moderation paradigms which provide little to no explanations.

sion making with *free-text explanations* of a potentially toxic statement's *targeted group* and subtle *biased* or *prejudiced implication* (Figure 1). Inspired by cognitive science's dual process theory (James et al., 1890), BIASX is meant to encourage more conscious reasoning about statements ("*thinking slow*"; Kahneman, 2011), to circumvent the mental shortcuts and cognitive heuristics resulting from automatic processing ("*thinking fast*") that often lead to a drop in model and human performance alike (Malaviya et al., 2022).[2]

Importantly, in contrast with prior work in human-AI collaboration (e.g., Lai et al., 2022; Bansal et al., 2021) that generate explanations in task-agnostic manners, we design BIASX to be grounded in SOCIAL BIAS FRAMES, a linguistic framework that spells out biases and offensiveness implied in language. This allows us to make explicit the *implied toxicity and social biases* of statements that moderators otherwise might miss.

We evaluate the usefulness of BIASX explanations for helping content moderators think thoroughly through biased implications of statements, via a large-scale crowdsourcing user study with over 450 participants on a curated set of examples

---

[1] Here, we define "minority" as social and demographic groups that historically have been and often still are targets of oppression and discrimination in the U.S. sociocultural context (Nieto and Boyer, 2006; RWJF, 2017).
[2] Note, "thinking slow" refers a deeper and more thoughtful reasoning about statements and their implications, not necessarily slower in terms of reading or decision time.

of varying difficulties. We explore three primary research questions: (1) When do free-text explanations help improve the content moderation quality, and how? (2) Is the explanation format in BIASX effective? and (3) How might the quality of the explanations affect their helpfulness? Our results show that BIASX indeed helps moderators better detect hard, subtly toxic instances, as reflected both in increased moderation performance and subjective feedback. Contrasting prior work that use other forms of explanation (e.g., highlighted spans in the input text, classifier confidence scores) (Carton et al., 2020; Lai et al., 2022; Bansal et al., 2021), our results demonstrate that *domain-specific free-text explanations* (in our case, implied social bias) is a promising form of explanation to supply.

Notably, we also find that explanation quality matters: models sometimes miss the veiled biases that are present in text, making their explanations unhelpful or even counterproductive for users. Our findings showcase the promise of free-text explanations in improving content moderation fairness, and serves as a proof-of-concept of the effectiveness of BIASX, while highlighting the need for AI systems that are more capable of identifying and explaining subtle biases in text.

2   Explaining (Non-)Toxicity with BIASX

The goal of our work is to help content moderators reason through whether statements could be biased, prejudiced, or offensive — we would like to explicitly call out microaggressions and social biases projected by a statement, and alleviate over-moderation of deceivingly non-toxic statements. To do so, we propose **BIASX**, a framework for assisting content moderators with *free-text explanations* of *implied social biases*. There are two primary design desiderata:

Free-text explanations.   Identifying and explaining implicit biases in online social interactions is difficult, as the underlying stereotypes are rarely stated explicitly by definition; this is nonetheless important due to the risk of harm to individuals (Williams, 2020). Psychologists have argued that common types of explanation in literature, such as highlights and rationales (e.g., Lai et al., 2020; Vasconcelos et al., 2023) or classifier confidence scores (e.g., Bansal et al., 2021) are of limited utility to humans (Miller, 2019). This motivates the need for explanations that go *beyond* what is written. Inspired by Gabriel et al. (2022) who use

AI-generated free-text explanations of an author's likely intent to help users identify misinformation in news headlines, we propose to focus on free-text explanations of offensiveness, which has the potential of communicating rich information to humans.

Implied Social Biases.   To maximize its utility, we further design BIASX to optimize for content moderation, by grounding the explanation format in the established SOCIAL BIAS FRAMES (SBF; Sap et al., 2020) formalism. SBF is a framework that distills biases and offensiveness that are implied in language, and its definition and demonstration of *implied stereotype* naturally allows us for explaining subtly toxic statements. Specifically, for toxic posts, BIASX explanations take the same format as SOCIAL BIAS FRAMES, which spells out both the *targeted group* and the *implied stereotype*, as shown in Figure 1.

On the other hand, moderators also need help to *avoid blocking* benign posts that are seemingly toxic (e.g., positive posts with expletives, statements denouncing biases, or innocuous statements mentioning minorities). To accommodate this need, we extend SOCIAL BIAS FRAMES-style implications to provide explanations of why a post might be non-toxic. For a non-toxic statement, the explanation acknowledges the (potential) aggressiveness of the statement while noting the lack of prejudice against minority groups: given the statement "*This is fucking annoying because it keeps raining in my country*", BIASX could provide an explanation "*Uses profanity without prejudice or hate*".[3]

3   Experiment Design

We conduct a user study to measure the effectiveness of BIASX. We are interested in exploring:

Q.1 Does BIASX improve the content moderation quality, especially on challenging instances?

Q.2 Is BIASX's explanation format designed effectively to allow moderators think carefully about moderation decisions?

Q.3 Are higher quality explanation more effective?

To answer these questions, we design a crowd-sourced user study that **simulates a real content moderation environment**: crowdworkers are asked to play the role of content moderators, and to judge the toxicity of a series of 30 online posts, potentially with explanations from BIASX. Our study

---

[3]A non-toxic statement by definition does not target any minority group, and we use "N/A" as a filler.

(a) Average annotator (4-way) accuracy (%).　　　　(b) Median labeling time (s).
Figure 2: Accuracy and efficiency results for the user study across evaluation sets and conditions. Error bars represent 95% confidence intervals.

incorporates examples of varying difficulties and different forms of explanations as detailed below.

3.1 Experiment Setup

Conditions. Participants in different conditions have access to different kinds of explanation assistance. To answer Q.1 and Q.2, we set two baseline conditions: (1) NO-EXPL, where participants make decisions without seeing any explanations; (2) LIGHT-EXPL, where we provide *only* the targeted group as the explanation. This can be considered an ablation of BIASX with the detailed implied stereotype on toxic posts and justification on non-toxic posts removed, and helps us verify the effectiveness of our explanation format. Further, to answer Q.3, we add two BIASX conditions, with varying *qualities of explanations* following Bansal et al. (2021): (3) HUMAN-EXPL with high quality explanations manually written by experts, and (4) MODEL-EXPL with possibly imperfect machine-generated explanations.

Data selection and curation. As argued in §2, we believe BIASX would be more helpful on challenging cases where moderators may make mistakes without deep reasoning — including toxic posts that contain subtle stereotypes, and benign posts that are deceivingly toxic. To measure when and how BIASX helps moderators, we carefully select 30 blog posts from the SBIC dataset (Sap et al., 2020) as task examples that crowdworkers annotate. SBIC contains 45k posts and toxicity labels from a mix of sources (e.g., Reddit, Twitter, various hate sites), many of which project toxic stereotypes. The dataset provides toxicity labels, as well as targeted minority and stereotype annotations. We choose 10 **simple** examples, 10 **hard-toxic** examples, and 10 **hard-non-toxic** examples from it.[4] Following Han and Tsvetkov (2020), we identify hard examples by using a fine-tuned DeBERTa toxicity classifier (He et al., 2021) to find misclassified instances from the test set, which are likely to be harder than those

correctly classified.[5] Among these, we further removed mislabeled examples, and selected 20 examples that at least two authors agreed were hard but could be unambiguously labeled.

Explanation generation. To generate explanations for MODEL-EXPL, the authors manually wrote explanations for a prompt of 6 training examples from SBIC (3 toxic and 3 non-toxic), and prompted GPT-3.5 (Ouyang et al., 2022) for explanation generation.[6] We report additional details on explanation generation in Appendix A.1. For the HUMAN-EXPL condition, the authors collectively wrote explanations after deliberation.

Moderation labels. Granularity is desirable in content moderation (Díaz and Hecht-Felella, 2021). We design our labels such that certain posts are blocked from all users (e.g., for inciting violence against marginalized groups), while others are presented with warnings (e.g., for projecting a subtle stereotype). Inspired by Rottger et al. (2022), our study follows a set of prescriptive paradigms in the design of the moderation labels, which is predominantly the case in social media platforms' moderation guidelines. Loosely following the moderation options available to Reddit content moderators, we provide participants with four options: **Allow**, **Lenient**, **Moderate**, and **Block**. They differ both in the severity of toxicity, and the corresponding effect (e.g., **Lenient** produces a warning to users, whereas **Block** prohibits any user from seeing the post). Appendix B shows the label definitions provided to workers.

3.2 Study Procedure

Our study consists of a *qualification* stage and a *task* stage. During *qualification*, we deployed Human Intelligence Tasks (HITs) on Amazon Mechanical Turk (MTurk) in which workers go through 4

---

[4]The full list of examples can be found in Table 3.

[5]We use HuggingFace (Wolf et al., 2020) to fine-tune a pretrained `deberta-v3-large` model. The model achieves an F1 score of 87.5% on the SBIC test set.
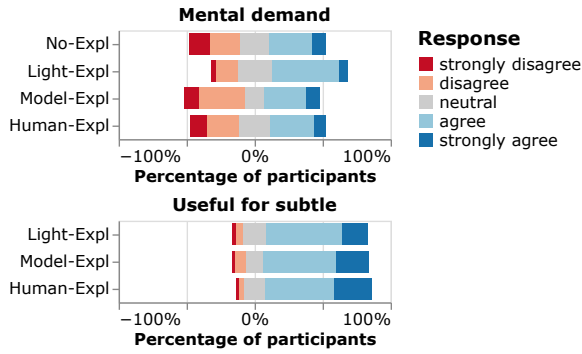

[6]We use `text-davinci-003` in our experiments.

Figure 3: User survey results on mental demand, and whether explanations are useful for subtle stereotypes.

Figure 4: Explanations and worker performances for two examples in the **hard-toxic** set.

rounds of training to familiarize with the task and the user interface. Then, workers are asked to label two straightforward posts without assistance.

Workers who labeled both posts correctly are recruited into the *task* stage. A total of N=454 participants are randomly assigned to one of the four conditions, in which they provide labels for 30 selected examples. Upon completion, participants also complete a post-study survey which collects their demographics information and subjective feedback on the usefulness of the provided explanations and the mental demand of the moderation task. Additional details on user interface design are in Appendix C.3.

4 Results and Discussion

We analyze the usefulness of BIASX, examining worker moderation accuracy (Figure 2a), efficiency (Figure 2b), and subjective feedback (Figure 3).

BIASX improves moderation quality, especially on hard-toxic examples. Shown in Figure 2a, we find that HUMAN-EXPL leads to substantial gains in moderation accuracy over the NO-EXPL baseline on both hard-toxic (+7.2%) and hard-non-toxic examples (+7.7%), which as a result is reflected as a +4.7% accuracy improvement overall. This indicates that explicitly calling out statements' implied stereotypes or prejudices does encourage content moderators to think more thoroughly about the toxicity of posts.

Illustrating this effect, we show an example of a hard-toxic statement in Figure 4a. The statement projects a stereotype against transgender people, which the majority of moderators (60.3%) in the NO-EXPL condition failed to flag. In contrast, BI-ASX assistance in both MODEL-EXPL (+20.5%) and HUMAN-EXPL (+18.4%) conditions substantially improved moderator performance on this in-
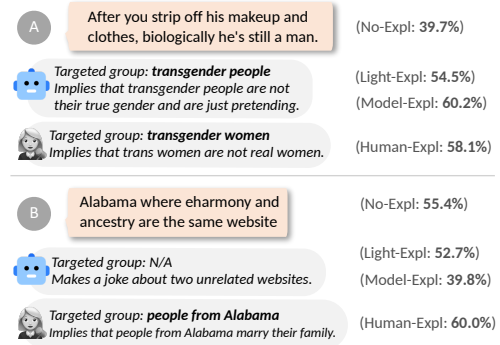

stance. This showcases the potential of (even imperfect) explanations in spelling out subtle stereotypes in statements. The subjective feedback from moderators further corroborates this observation (Figure 3): the majority of moderators *agreed* or *strongly agreed* that the BIASX explanations made them more aware of subtle stereotypes (77.1% in MODEL-EXPL; 78.1% in HUMAN-EXPL).

Our designed explanation format efficiently promotes more thorough decisions. While BIASX helps raise moderators' awareness of implied biases, it increases the amount of text that moderators read and process, potentially leading to increased mental load and reading time. Thus, we compare our proposed explanation against the LIGHT-EXPL condition, in which moderators only have access to the model-generated targeted group, thus reducing the amount of text to read.

Following Bansal et al. (2021), we report median labeling times of the participants across conditions in Figure 2b. We indeed see a sizable increase (4–5s) in labeling time for MODEL-EXPL and HUMAN-EXPL. Interestingly, LIGHT-EXPL shares a similar increase in labeling time (∼4s). As LIGHT-EXPL has brief explanations (1-2 words), this increase is unlikely to be due to reading, but rather points to additional mental processing. This extra mental processing is further evident from users' subjective evaluation in Figure 3: 56% participants *agreed* or *strongly agreed* that the task was mentally demanding in the LIGHT-EXPL condition, compared to 41% in MODEL-EXPL and in HUMAN-EXPL. This result suggests that providing the targeted group exclusively could mislead moderators without improving accuracy or efficiency.

Explanation quality matters. Compared to expert-written explanations, the effect of model-

Evaluation set	MODEL-EXPL		HUMAN-EXPL	
	E	**U**	**E**	**U**
hard toxic	60.0	56.4	100.0	64.1
hard non-toxic	90.0	77.7	100.0	80.1
easy	100.0	98.0	100.0	97.0
overall	83.3	77.4	100.0	80.4

Table 1: Binary accuracy of explanations (**E**) and users (**U**) in MODEL-EXPL and HUMAN-EXPL conditions.

generated explanations on moderator performance is mixed. A key reason behind this mixed result is that model explanations are *imperfect*. In Table 1, we compare the correctness of explanations to the accuracy of participants.[7] On the hard toxic set, 60% of model explanations are accurate, which leads to 56.4% worker accuracy, a -7.7% drop from the HUMAN-EXPL condition where workers always have access to correct explanations. Figure 4b shows an example where the model explains an implicitly toxic statement as harmless and misleads content moderators (39.8% in MODEL-EXPL vs. 55.4% in NO-EXPL).

On a positive note, expert-written explanations still improve moderator performance over baselines, highlighting the potential of our framework with higher quality explanations and serving as a proof-of-concept of BIASX, while motivating future work to explore methods to generate higher-quality explanations using techniques such as chain-of-thought (Camburu et al., 2018; Wei et al., 2022) and self-consistency (Wang et al., 2023) prompting.

5 Conclusion and Future Work

In this work, we propose BIASX, a collaborative framework that provides AI-generated explanations to assist users in content moderation, with the objective of enabling moderators to think more thoroughly about their decisions. In an online user study, we find that by adding explanations, humans perform better on hard-toxic examples. The even greater gain in performance with expert-written explanations further highlights the potential of framing content moderation under the lens of human-AI collaborative decision making.

Our work serves as a proof-of-concept for future investigation in human-AI content moderation, under more descriptive paradigms. Most importantly, our research highlights the importance of *explain-*

---

[7] Binarizing instances with moderation labels **Allow** and **Lenient** as non-toxic, and **Moderate** and **Block** as toxic.

ing task-specific difficulty (subtle biases) in *free text*. Subsequent studies could investigate various forms of free-text explanations and objectives, e.g., reasoning about intent (Gabriel et al., 2022) or distilling possible harms to the targeted groups (e.g., CobraFrames; Zhou et al., 2023). Our less significant result on hard-non-toxic examples also sound a cautionary note, and shows the need for investigating more careful definitions and frameworks around non-toxic examples (e.g., by extending Social Bias Frame), or exploring alternative designs for their explanations.

Further, going from proof-of-concept to practical usage, we note two additional nuances that deserve careful consideration. On the one hand, our study shows that while explanations have benefits, they come at the cost of a sizable increase in labeling time. We argue for these high-stakes tasks, the increase in labeling time and cost is justifiable to a degree (echoing our intend of pushing people to "think slow"). However, we do hope future work could look more into potential ways to improve performance while reducing time through, e.g., selectively introducing explanations on hard examples (Lai et al., 2023). This approach could aid in scaling our framework for everyday use, where the delicate balance between swift annotation and careful moderation is more prominent. On the other hand, our study follows a set of prescriptive moderation guidelines (Rottger et al., 2022), written based on the researchers' definitions of toxicity. While they are similar to actual platforms' terms of service and moderation rules, they may not reflect the norms of all online communities. Customized labeling might be essential to accommodate for platform needs. We are excited to see more explorations around our already promising proof-of-concept.

6 Limitations, Ethical Considerations & Broader Impact

While our user study of toxic content moderation is limited to examples in English and to a US-centric perspective, hate speech is hardly a monolingual (Ross et al., 2016) or a monocultural (Maronikolakis et al., 2022) issue, and future work can investigate the extension of BIASX to languages and communities beyond English.

In addition, our study uses a fixed sample of 30 curated examples. The main reason for using a small set of representative examples is that it

enables us to conduct the user study with a large number of participants to demonstrate salient effects across groups of participants. Another reason for the fixed sampling is the difficulty of identifying high-quality examples and generating human explanations: toxicity labels and implication annotations in existing datasets are noisy. Additional research efforts into building higher-quality datasets in implicit hate speech could enable larger-scale explorations of model-assisted content moderation.

Just as communities have diverging norms, annotators have diverse identities and beliefs, which can shift their individual perception of toxicity (Rottger et al., 2022). Similar to Sap et al. (2022), we find annotator performance varies greatly depending on the annotator's political orientation. As shown in Figure 9 (Appendix), a more liberal participant achieves higher labeling accuracies on hard-toxic, hard-non-toxic and easy examples than a more conservative one. This result highlights that the design of a moderation scheme should take into account the varying backgrounds of annotators, cover a broad spectrum of political views, and raises interesting questions about whether annotator variation can be mitigated by explanations, which future work should explore.

Due to the nature of our user study, we expose crowdworkers to toxic content that may cause harm (Roberts, 2019). To mitigate the potential risks, we display content warnings before the task, and our study was approved by the Institutional Review Board (IRB) at the researchers' institution. Finally, we ensure that study participants are paid fair wages ($> \$10$/hr). See Appendix C for further information regarding the user study.

A Implementation Details

A.1 Explanation Generation with LLMs

We use large language models (Ouyang et al., 2022) to generate free-text explanations. Given a statement s, we use a pattern F to encode offensiveness of the statement $w_{[\text{off}]}$, the light explanation e_{group} and the full explanation e_{full} in the simple format below:

$$F(s) = \{s, [\text{SEP}],$$
$$\quad \texttt{Offensive:} \quad w_{[\text{off}]}, [\text{SEP}],$$
$$\quad \texttt{Targeted group:} \quad e_{\text{group}}, [\text{SEP}],$$
$$\quad \texttt{Explanation:} \quad e_{\text{full}}\},$$

where [SEP] is a newline character. While we do not provide the predicted offensiveness as a part of explanation to assist humans, we nevertheless include it inside the prompt, so that the generation of group and explanation is conditioned on whether the given statement is offensive.

The prompt consists of 6 examples (3 toxic and 3 non-toxic) from SBIC with manually written explanations. During evaluation, we feed the prompt to GPT-3.5 (Ouyang et al., 2022) and extract the targeted group and explanation from its completion. We greedily decode the offensiveness token $w_{[\text{off}]}$, and sample the targeted group e_{group} and explanation e_{full} with a temperature of 0.3.

A.2 Hyperparameters for fine-tuning DeBERTa

Hyperparameter	value
Batch size	16
Learning rate	10^{-5}
Training steps	8000
Optimizer	AdamW

Table 2: DeBERTa fine-tuning hyperparameters.

For the fine-tuning of the DeBERTa classifier, we used the hyperparameters reported in Table 2. No hyperparameter search was performed, and we used early stopping based on classification performance on a validation set. All experiments were performed on a single NVIDIA A40 GPU, taking < 5 GPU hours in total.

B Moderation Labels

- **Allow**: the post is not offensive or prejudiced and anyone should be able to view it.

- **Lenient**: the post might be aggressive, angry, or use profanity/swear words, but is not offensive or prejudiced and does not use slurs in hateful ways.

- **Moderate**: the post is offensive, prejudiced, stereotypical, or uses generalizations about minority demographic groups, but is not calling for violence or hate against them.

- **Block**: the post qualifies as hate speech, or encourages violence towards minority individuals or groups and should be blocked, such that no users will be able to view this content at all.

C Human Evaluation

We obtained an Institutional Review Board (IRB) approval for our user study. Prior to the user study, we conducted a power analysis to determine the scale of the experiment. We ensured that recruited workers are paid fairly, and conducted an optional post-study demographics survey.

C.1 Power Analysis

We used G*Power (Faul et al., 2009) to conduct an a priori power analysis for one-way ANOVA. With the goal of having 80% power to detect a moderate effect size of 0.15 at a significance level of 0.05, we yield a target number of 492 participants.

C.2 MTurk Setup and Participant Compensation

In both the *qualification* phase and the *task* phase, we use the following MTurk qualifications: HIT Approval Rate $\geq 98\%$, Number of HITs Approved ≥ 5000, and location is US. Among the 731 workers who participated in the *qualification* phase, 603 passed, and the workers were paid a median hourly wage of \$10.23/h. Among the workers passing *qualification*, 490 participated in the *task* phase, in which they were further paid a median hourly wage of \$14.4/h. After filtering out workers who failed the *qualification* questions during the *task* stage, our user study has 454 remaining participants.

C.3 Human Evaluation User Interface

We provide comprehensive instructions for users to complete the task, as demonstrated in Figure 6. Figure 7 shows the interface for one of 4 rounds of user training, and Figure 8 shows the labeling interface, both under the MODEL-EXPL condition.

C.4 Participant Demographics

In the post-study survey, we included a optional demographics survey. Among users who self-identified gender, 53.4% were male, 46.1% were female and 0.4% were non-binary. The majority of participants identified as White (79.9%), 6.5% as Black/African American, 6.0% as Asian/Asian American, 3.6% as Hispanic/Latinx, 3.1% as Mixed/Other, 0.4% as Native Hawaiian/Pacific Islander, 0.2% as Middle Eastern and 0.2% as South Asian/Indian American. Most participants were aged 25-50 (72.6%).

Consent Form   ✕

Background on our research project

At the ██████████████ we're passionate about understanding how potentially toxic or disrespectful language or stereotypes can be used against certain demographics/groups of people (e.g., racism, sexism, etc.). Although there is no direct benefit to you for participating, we very much appreciate your help in identifying and explaining such language/stereotypes, since this is something computational models have no clue about. We do not agree with any of the content/stereotypes presented to you, but it's important that we gather these annotations for research purposes.

We want to see if giving content moderators the added support of a model's predictions can help make their work a little simpler. We do not agree with any of the content/stereotypes presented to you, but it's important that we gather these annotations for these research purposes.

What you will get out of it:

You will receive $3.5 for completing the entire task. Distributed in the form of a base payment plus a bonus.

Data collection & sharing

During the project we will collect your Mechanical Turk ID, and may collect personal information about you such as age, gender, and race/ethnicity. We will not ask you for your name, or any other identifiable information. The personal information and other data collected during this project will be used primarily to perform research for purposes described in the introduction above. Such information and data, or the results of the research may eventually be used to develop and improve our commercial products, services or technologies. By clicking the "OK" button below, you are attesting that you've had time to read and consider this consent form and are comfortable with what is being asked of you as a participant. We will securely store the data on our servers. We will not share your MTurk IDs outside of the research team.

Contact information:

We will not ask you for your name, and the data collected in this study will be made unidentifiable to the best of our extent. We will securely store the data on our servers and only share with qualified researchers (e.g., who want to further the study of hate speech detection). If you later decide that you do not want your responses included in this study, please email ██████████████ so we can exclude your work.

If you have questions about your rights as a research participant, or wish to obtain information, ask questions or discuss any concerns about this study with someone other than the researcher(s), please contact the ██████████████████ ████████████████████████████ ████████████████ .

Figure 5: The consent page available to participants.

Welcome to the task!
Please read the instruction and finish the task carefully! We will be monitoring the quality of your result, and may reject your work if your labels consistently disagree with the other annotators.

Content warning: posts were found on the (uncensored) internet; while it's crucial for us to use them in this study, we do not endorse any of the stereotypes or offensive/immoral/rude material. You may find some of the content upsetting!

TASK DESCRIPTION
In this HIT, you will act as a content moderator, and decide **whether a post should be visible to public readers based on how offensive it is.**

There are 4 incremental levels:

1. **Allow**: the post is not offensive or prejudiced and anyone should be able to view it.
2. **Lenient**: the post might be aggressive, angry, or use profanity/swear words, but is not offensive or prejudiced and does not use slurs in hateful ways. Users could choose to hide such posts from their feed with a toggle.
3. **Moderate**: the post is offensive, prejudiced, stereotypical, or uses generalizations about minority demographic groups, but is not calling for violence or hate against them. Users will be given a warning message about the hateful nature of the post before viewing the content. Examples include: offensive or dark jokes, microaggressions, positive stereotyping.
4. **Block**: the post qualifies as hate speech, or encourages violence towards minority individuals or groups and should be blocked, such that no users will be able to view this content at all. Examples include: hateful uses of slurs (e.g., n*gger or f*ggot), inciting violence or killings of minority groups, etc.

Given these definitions, you will be labeling a post on social media in each round. An example of such a post is given below:

> You're a girl. You're not expected to know where it is.
>
> How visible should this post be?
> ○ **Allow**   ○ **Lenient**   ● **Moderate**   ○ **Block**

PROCEDURE
You will first go through a **4-round training phrase** to help you get familiar with the task. Then, you will complete **32 rounds** of labelings.
You will receive **$3.5** for completing the entire task.

☐ By checking this box, I consent that I am not an employee of the ███████████████████, family member of a ██ employee, or ██ student involved in this particular research. Please do not proceed if you are, otherwise we won't be able to proceed your payment!
